

# Network Layer: “data plane” roadmap

- Network layer service
- Networks layer: Internet
- IP Protocol
- IP Addressing
- DHCP
- Network Address Translation (NAT)

# Network-layer services and protocols

- transport segment from sending to receiving host
  - **sender**: encapsulates segments into datagrams, passes to link layer
  - **receiver**: delivers segments to transport layer protocol
- network layer protocols in *every Internet device*: hosts, routers
- **routers**:
  - examines header fields in all IP datagrams passing through it
  - moves datagrams from input ports to output ports to transfer datagrams along end-end path

# Two key network-layer functions

## network-layer functions:

- *forwarding*: move packets from a router's input link to appropriate router output link
- *routing*: determine route taken by packets from source to destination
  - *routing algorithms*

## analogy: taking a trip

- *forwarding*: process of getting through single interchange
- *routing*: process of planning trip from source to destination

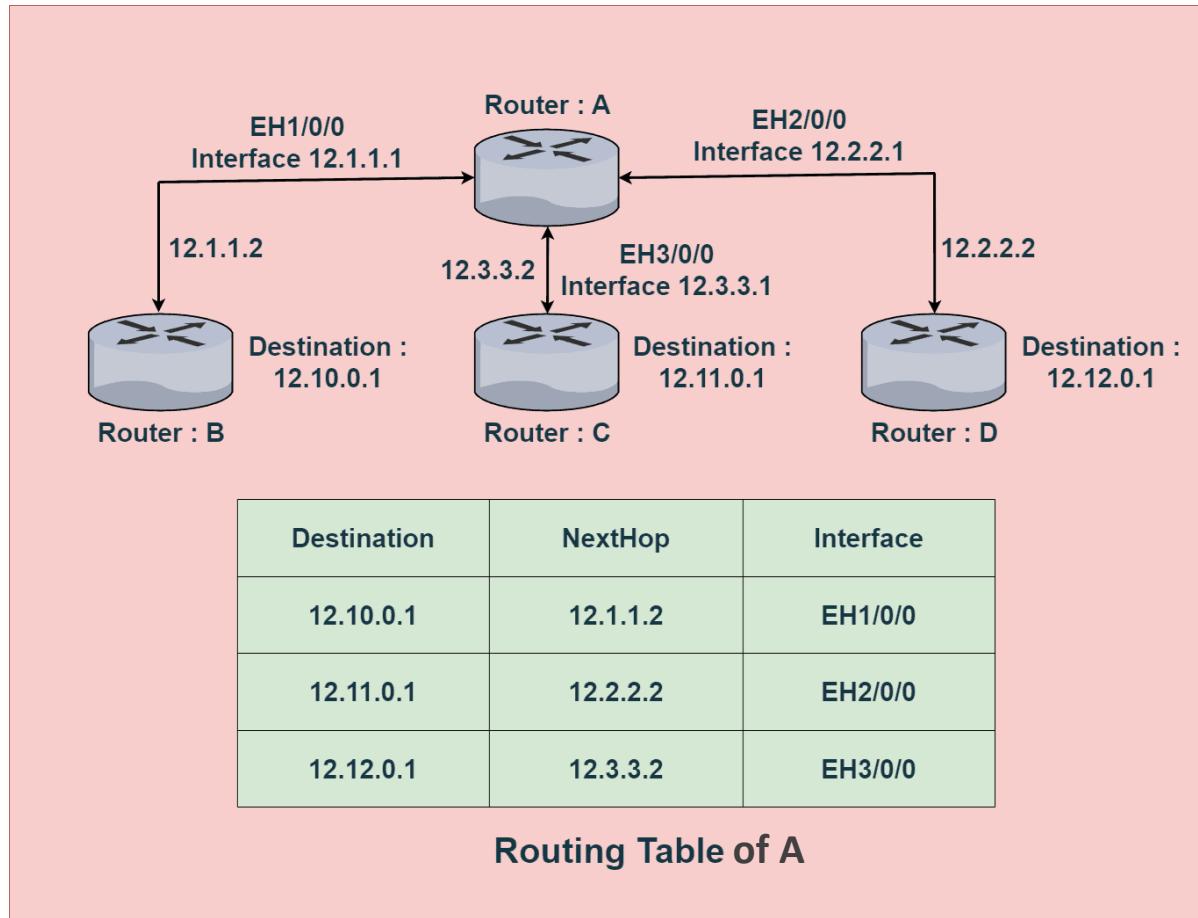

forwarding

routing

# Forwarding vs Routing

# Network-layer service model

Network Architecture	Service Model	Quality of Service (QoS) Guarantees ?			
		Bandwidth	Loss	Order	Timing
Internet	best effort	none	no	no	no

Internet “best effort” service model

*No* guarantees on:

- i. successful datagram delivery to destination
- ii. timing or order of delivery
- iii. bandwidth available to end-end flow

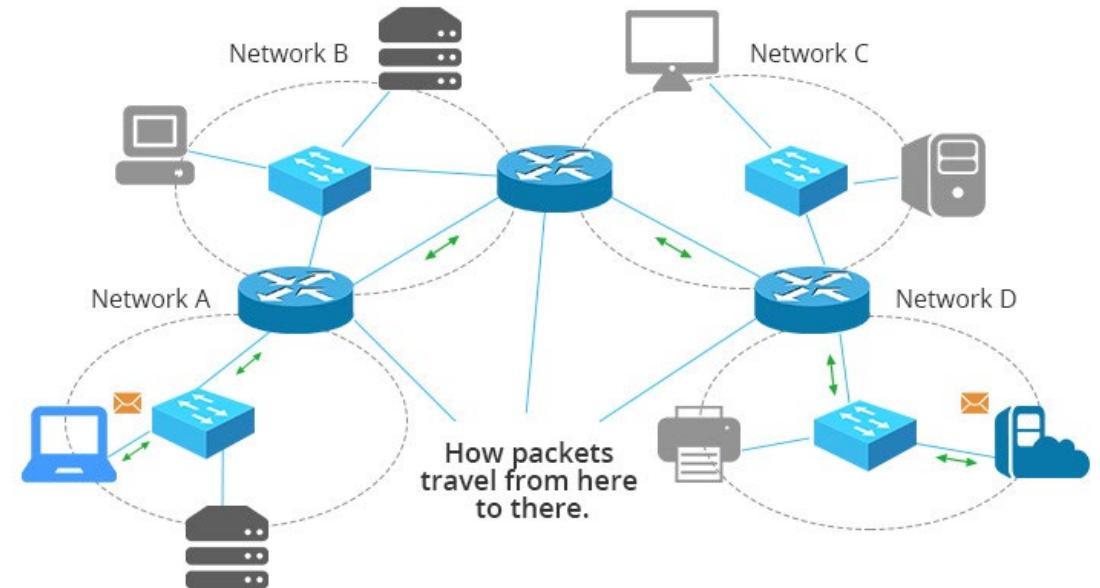

# Reflections on best-effort service:

- **simplicity of mechanism** has allowed Internet to be widely adopted
- sufficient provisioning of bandwidth allows performance of real-time applications (e.g., interactive voice, video) to be “good enough” for “most of the time”
- replicated, application-layer distributed services (datacenters, content distribution networks) connecting close to clients’ networks, allow services to be provided from multiple locations
- congestion control of “elastic” services helps

*It's hard to argue with success of best-effort service model*

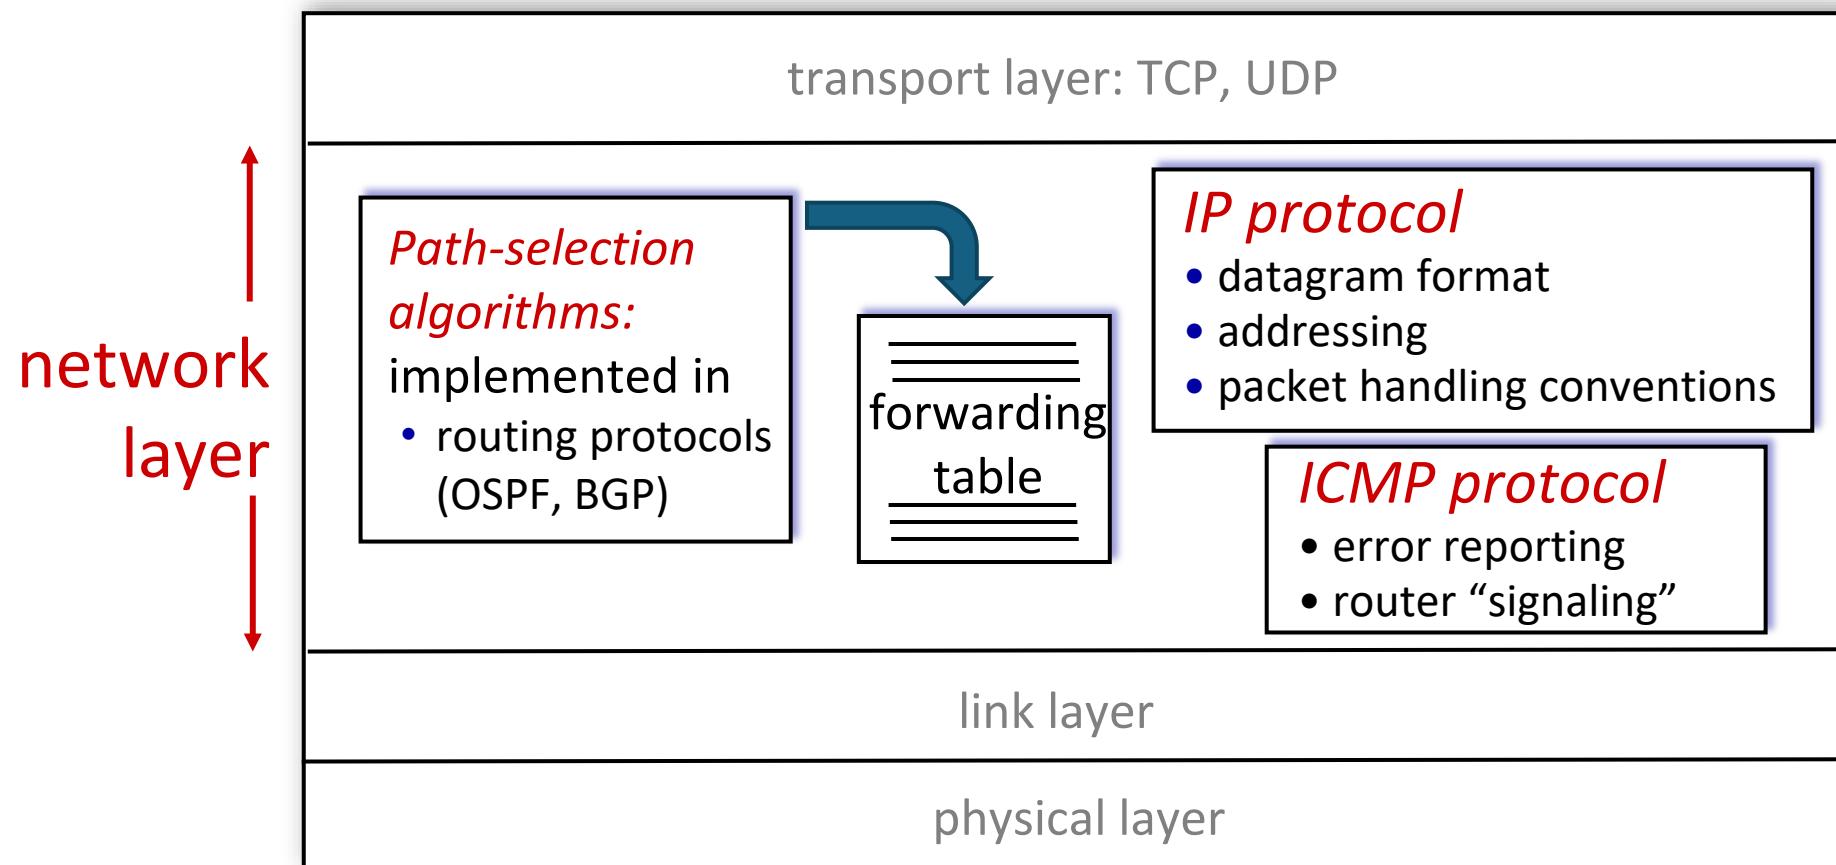

# Network Layer: “data plane” roadmap

- Network layer functions
- Service model
- Networks layer: Internet
- IP Protocol
- IP Addressing
- DHCP
- Network Address Translation (NAT)

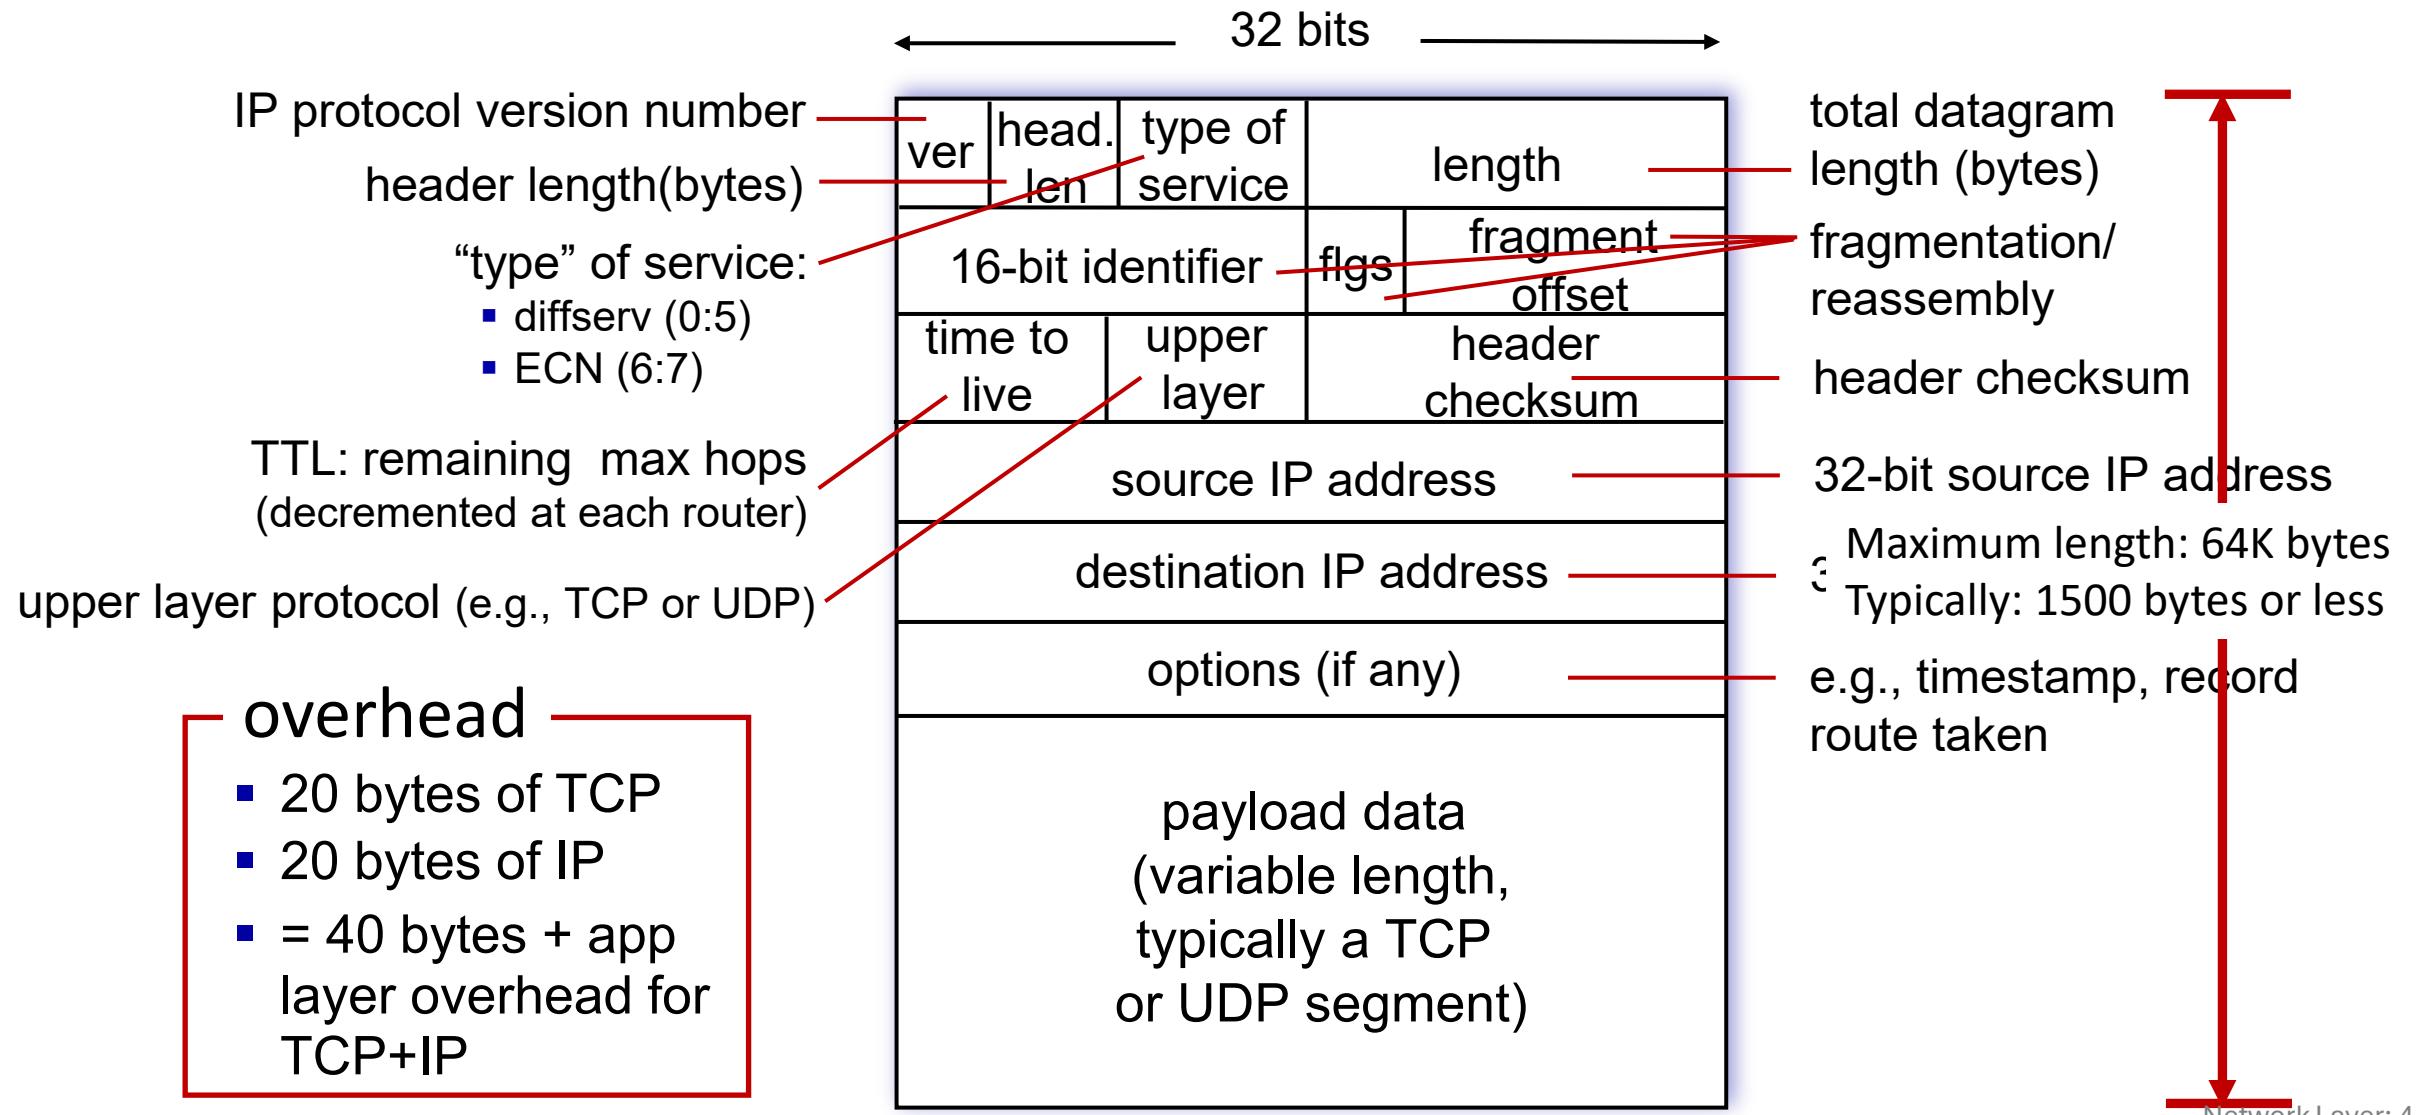

# Network Layer: Internet

host, router network layer functions:

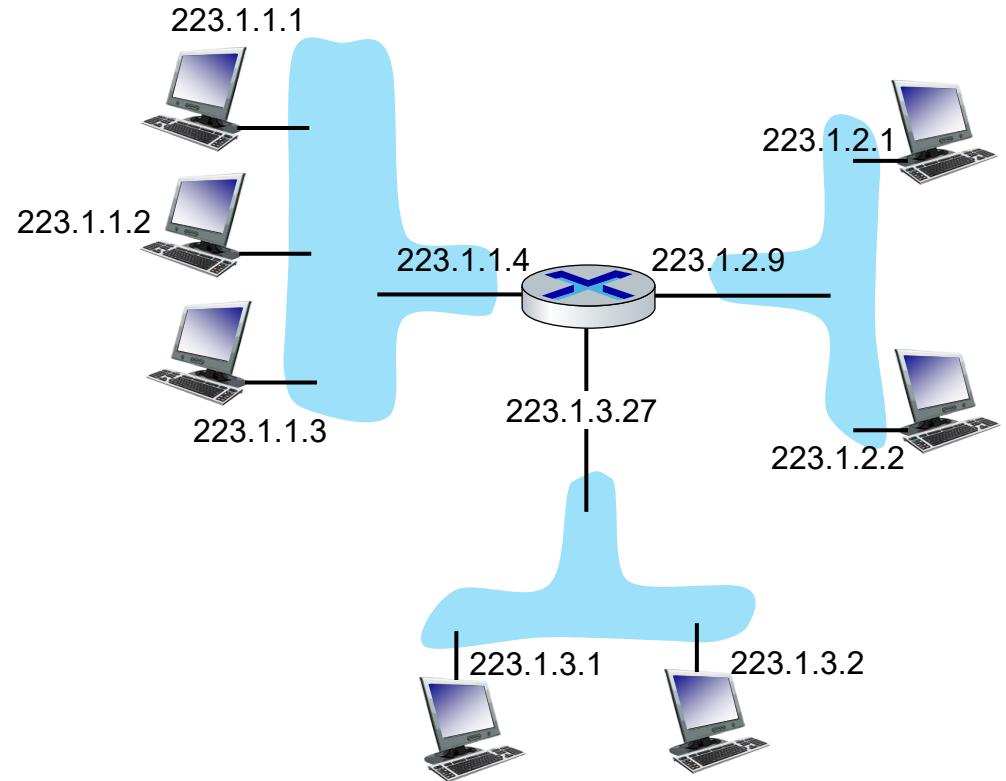

# IP Datagram format

# IP addressing: introduction

- **IP address:** 32-bit identifier associated with each host or router *interface*
- **interface:** connection between host/router and physical link
  - router's typically have multiple interfaces
  - host typically has one or two interfaces (e.g., wired Ethernet, wireless 802.11)

dotted-decimal IP address notation:

223.1.1.1 =  $\begin{array}{cccc} 11011111 & 00000001 & 00000001 & 00000001 \end{array}$

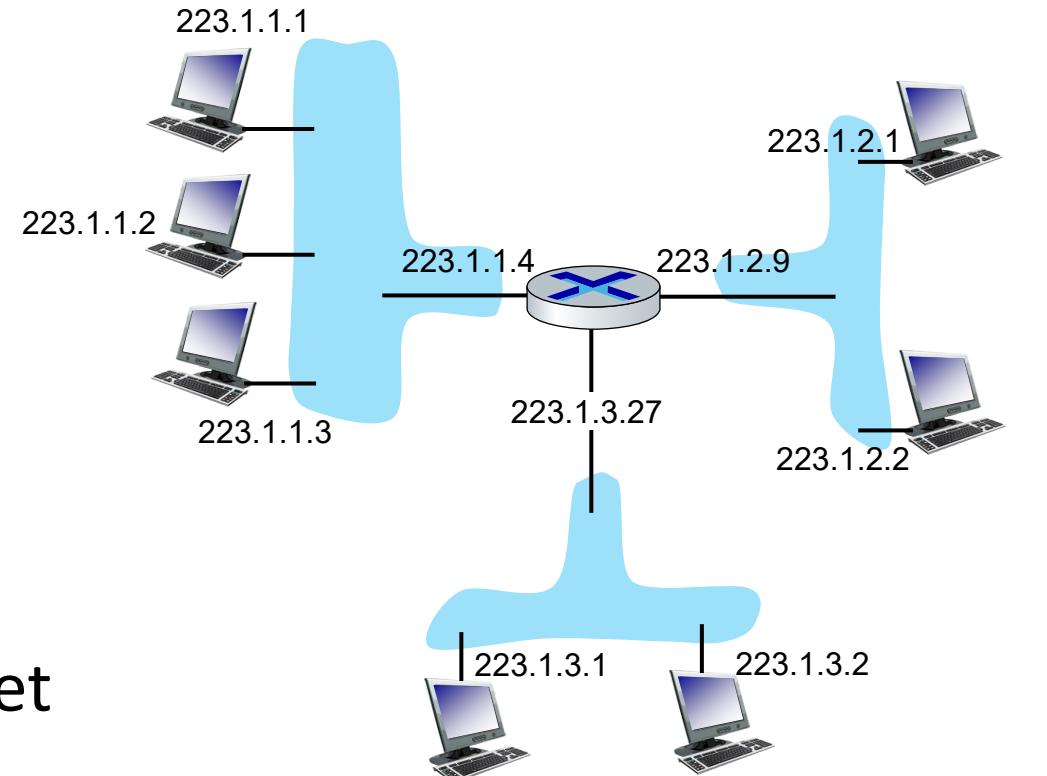

# Subnets

- *What's a subnet ?*

- device interfaces that can physically reach each other **without passing through an intervening router**

- IP addresses have structure:

- **subnet part:** devices in same subnet have common high order bits
- **host part:** remaining low order bits

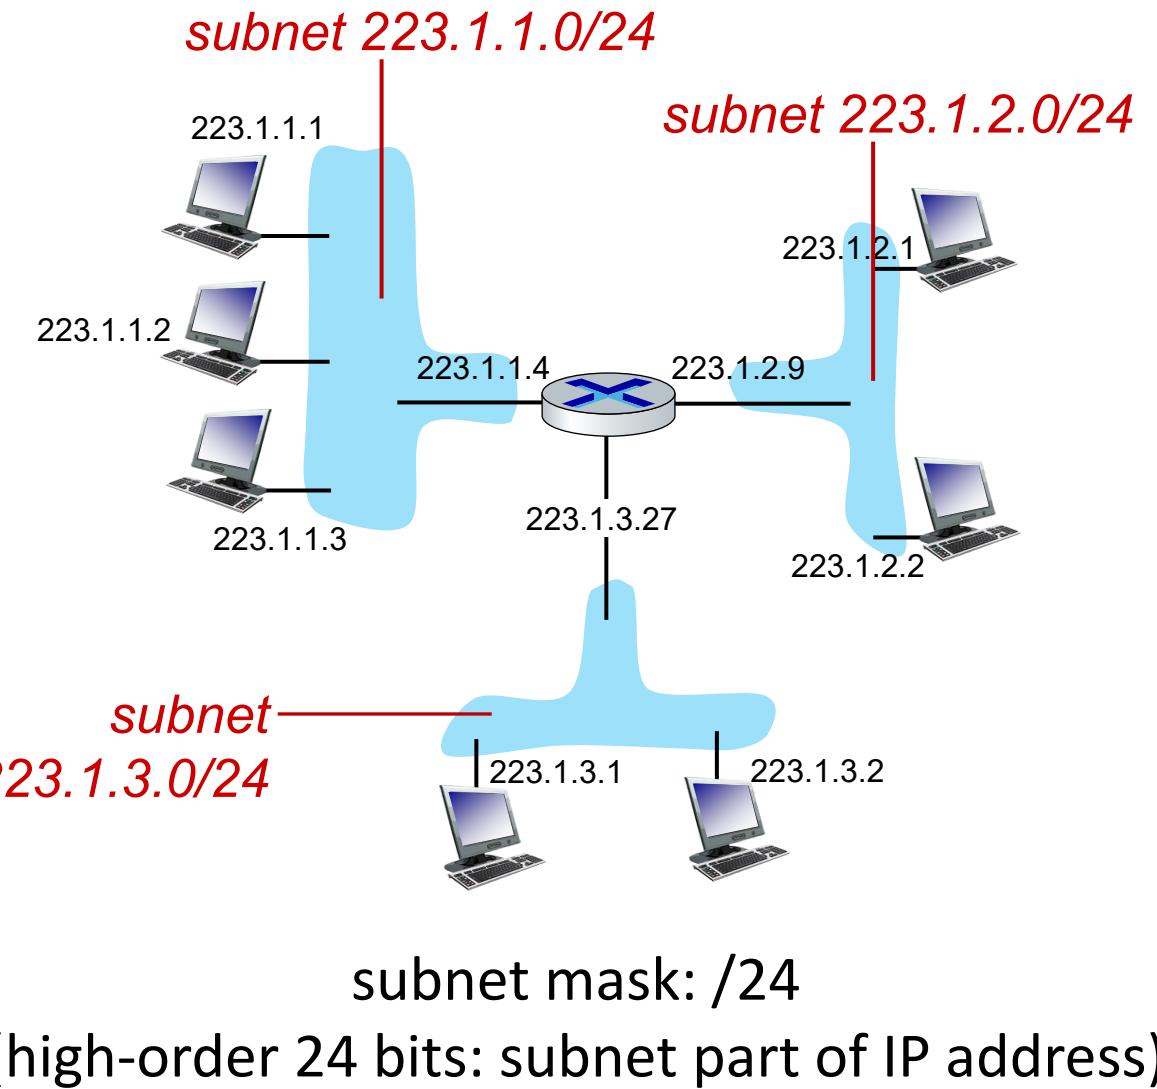

network consisting of 3 subnets

# Subnets

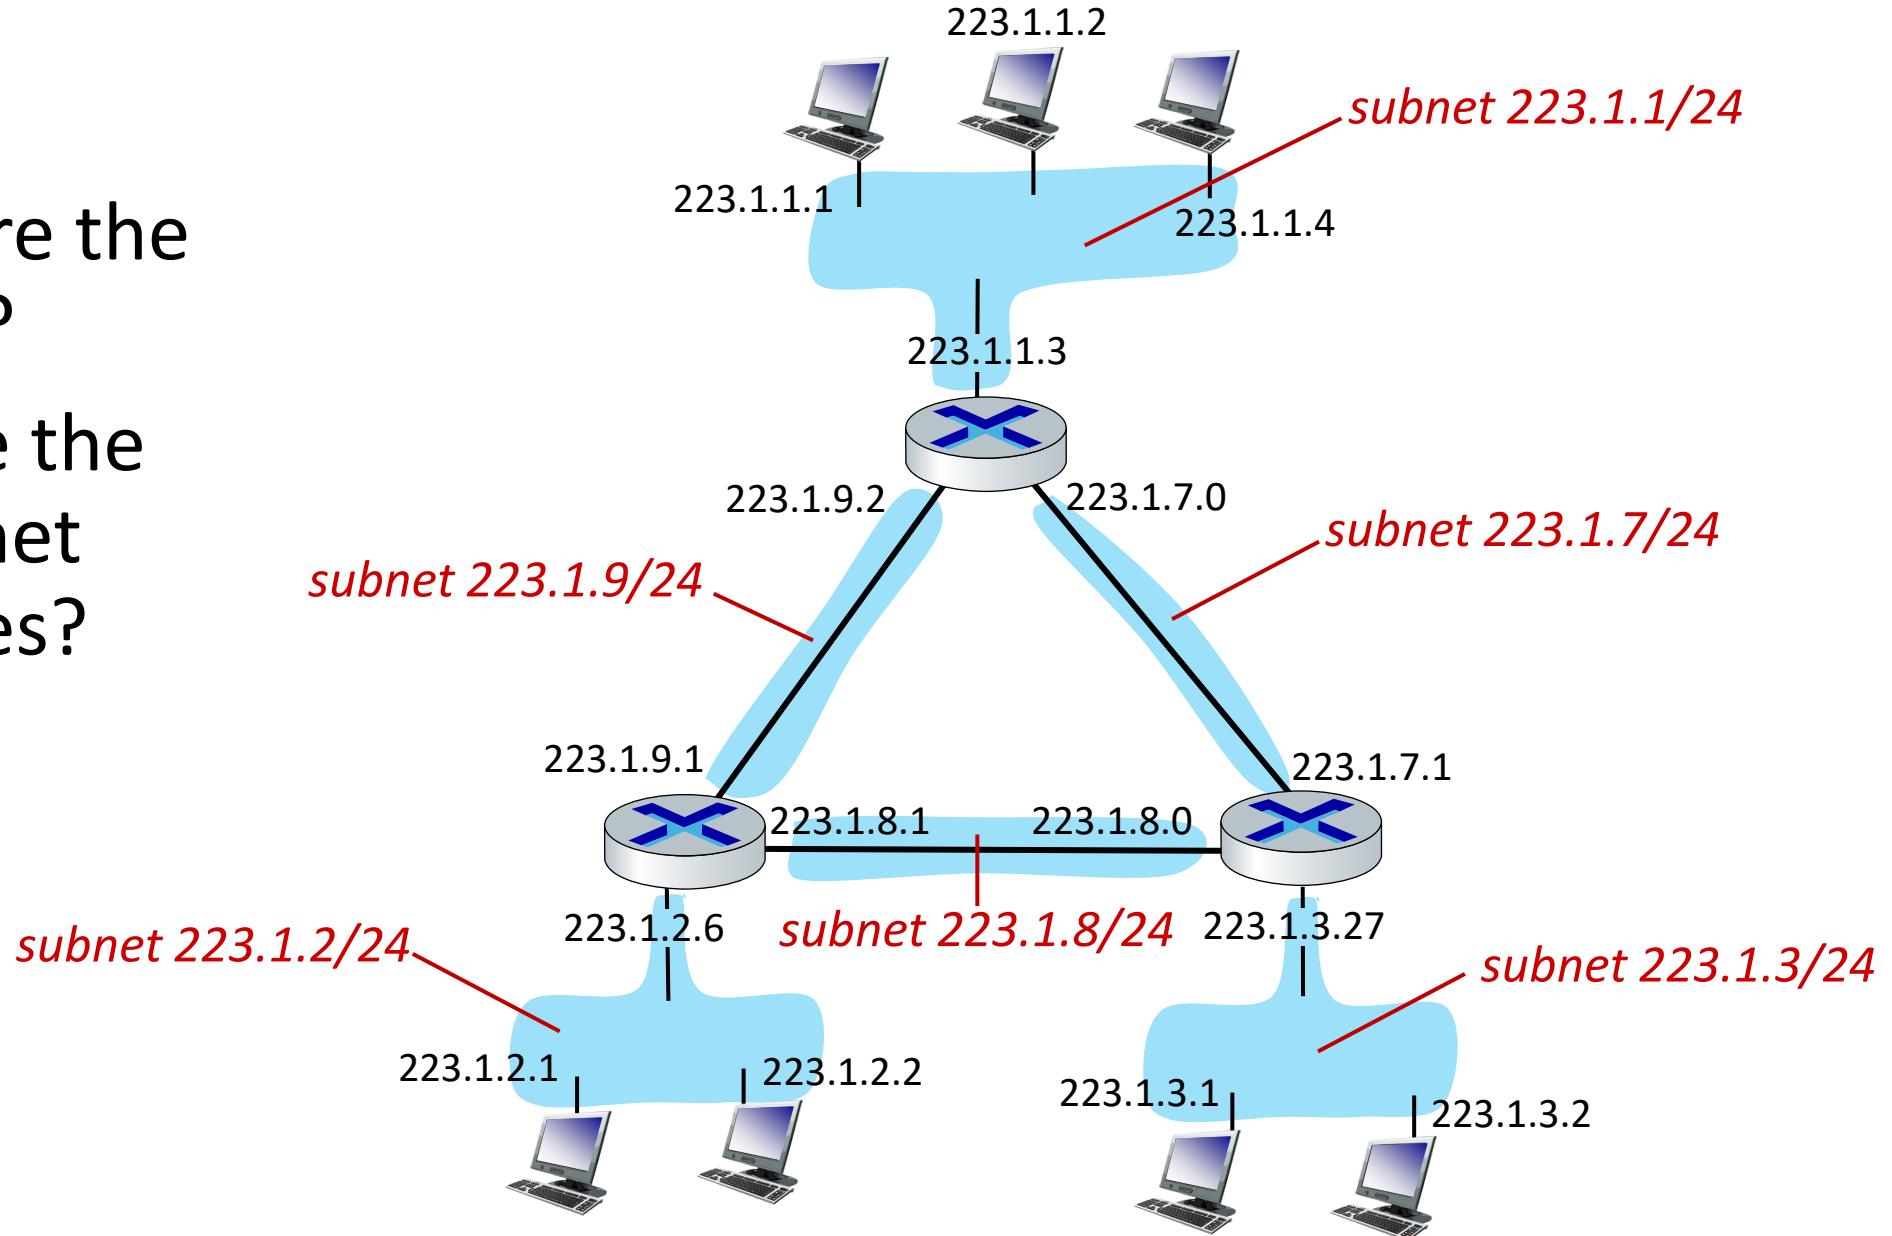

*Recipe for defining subnets:*

- detach each interface from its host or router, creating “islands” of isolated networks
- each isolated network is called a *subnet*

# Subnets

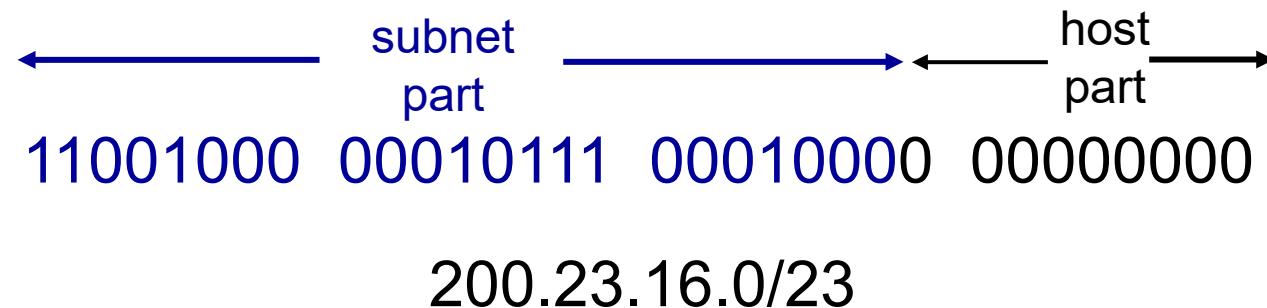

- where are the subnets?
- what are the /24 subnet addresses?

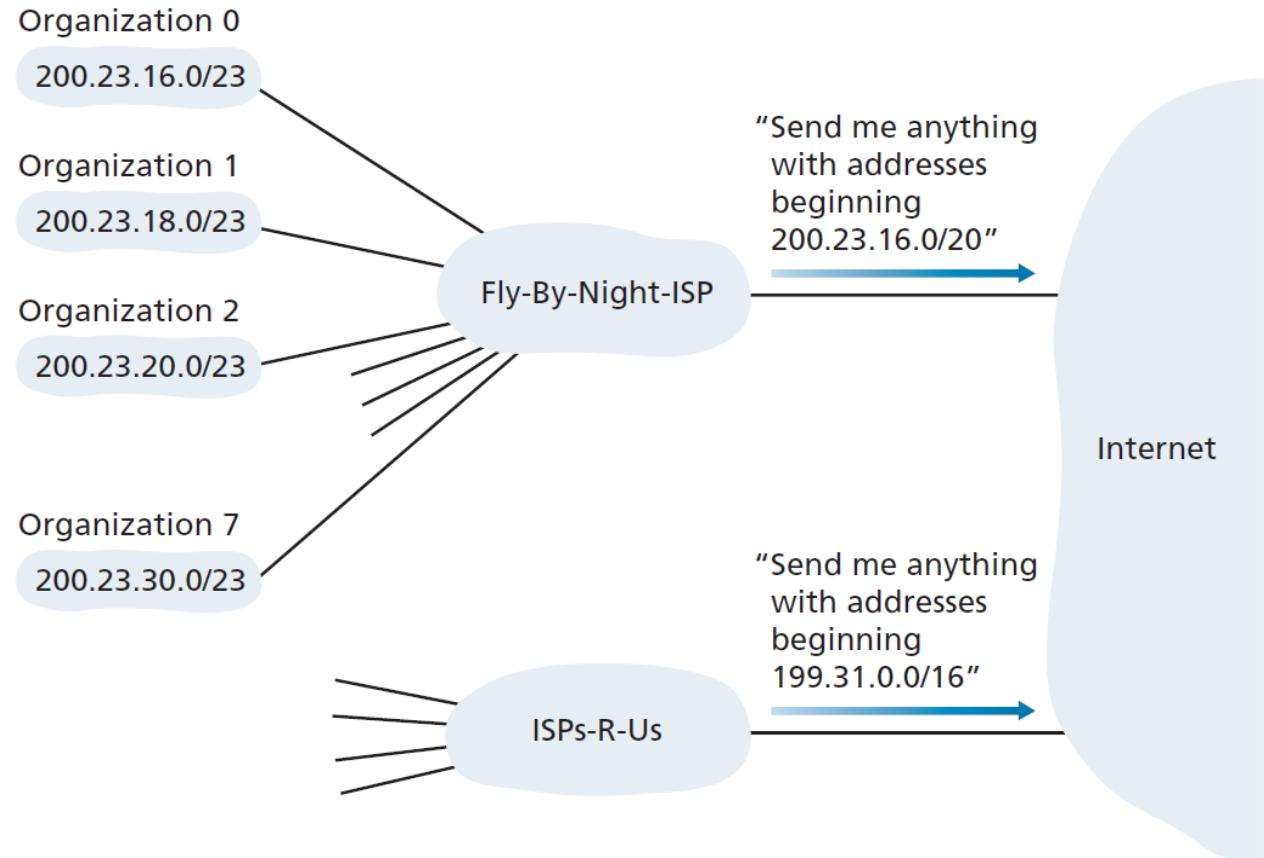

# IP addressing: CIDR

CIDR: Classless InterDomain Routing (pronounced “cider”)

- subnet portion of address of arbitrary length
- address format:  $a.b.c.d/x$ , where  $x$  is # bits in subnet portion of address

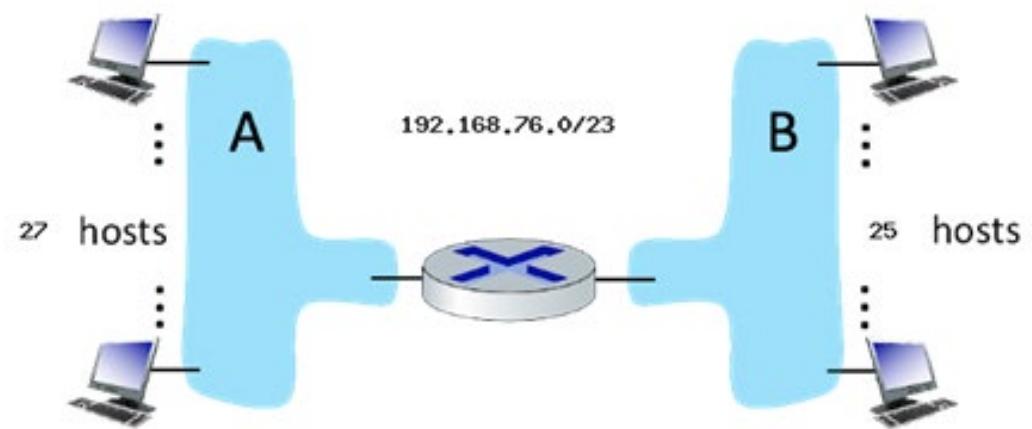

# Hierarchical Addressing under CIDR

**Figure 4.21** ◆ Hierarchical addressing and route aggregation

# Exercise: Allocating Addresses to Subnets

- How does the organization with network address 192.168.76.0/23 allocate addresses to two of its subnets A and B?
- Always allocate the larger subnet first (descending order)
- Subnet A
  - Subnet address 192.168.76.0/27
  - First 192.168.76.1
  - Last 192.168.76.30
  - Subnet broadcast 192.168.76.31
- Subnet B - Exercise

# Longest prefix matching

longest prefix match

when looking for forwarding table entry for given destination address, use *longest* address prefix that matches destination address.

	Destination Address Range				Link interface
200.23.16/21	11001000	00010111	00010***	*****	0
200.23.24/24	11001000	00010111	00011000	*****	1
200.23.24/21	11001000	00010111	00011***	*****	2
	otherwise				3

Exercise:

11001000 00010111 00010110 10100001 which interface?  
11001000 00010111 00011000 10101010 which interface?

# Longest prefix matching

## longest prefix match

when looking for forwarding table entry for given destination address, use *longest* address prefix that matches destination address.

Destination Address Range	Link interface
11001000 00010111 00010*****	0
11001000 00010111 00011000 *****	1
11001000 1 00011*** *****	2
otherwise	3

examples:

11001000 00010111 00010110 10100001 which interface?

11001000 00010111 00011000 10101010 which interface?

# Longest prefix matching

## longest prefix match

when looking for forwarding table entry for given destination address, use *longest* address prefix that matches destination address.

Destination Address Range					Link interface
11001000	00010111	00010***	*****	*	0
11001000	00010111	00011000	*****	*	1
11001000	00010111	00011***	*****	*	2
otherwise					3

match!

examples:

11001000	00010111	00010110	10100001	which interface?
11001000	00010111	00011000	10101010	which interface?

# Longest prefix matching

longest prefix match

when looking for forwarding table entry for given destination address, use *longest* address prefix that matches destination address.

Destination Address Range					Link interface
11001000	00010111	00010***	*****	*	0
11001000	00010111	00011000	*****	*	1
11001000	00010111	00011***	*****	*	2
otherwise					3

match!

examples:

11001000	00010111	00010110	10100001	which interface?
11001000	00010111	00011000	10101010	which interface?

# IP addresses: how to get one?

That's actually **two** questions:

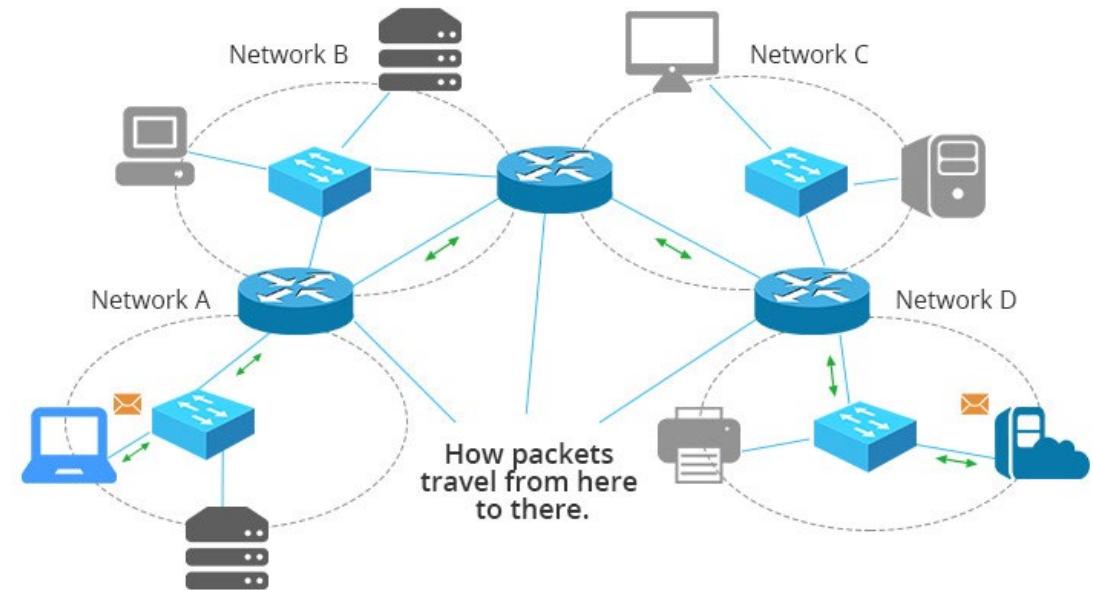

1. Q: How does a *host* get IP address within its network (host part of address)?
2. Q: How does a *network* get IP address for itself (network part of address)

How does *host* get IP address?

- hard-coded by sysadmin in config file (e.g., `/etc/rc.config` in UNIX)
- **DHCP: Dynamic Host Configuration Protocol:** dynamically get address from server
  - “plug-and-play”

# Network Layer: “data plane” roadmap

- Network layer functions
- Service model
- Networks layer: Internet
- IP Protocol
- IP Addressing
- DHCP
- Network Address Translation (NAT)

# DHCP: Dynamic Host Configuration Protocol

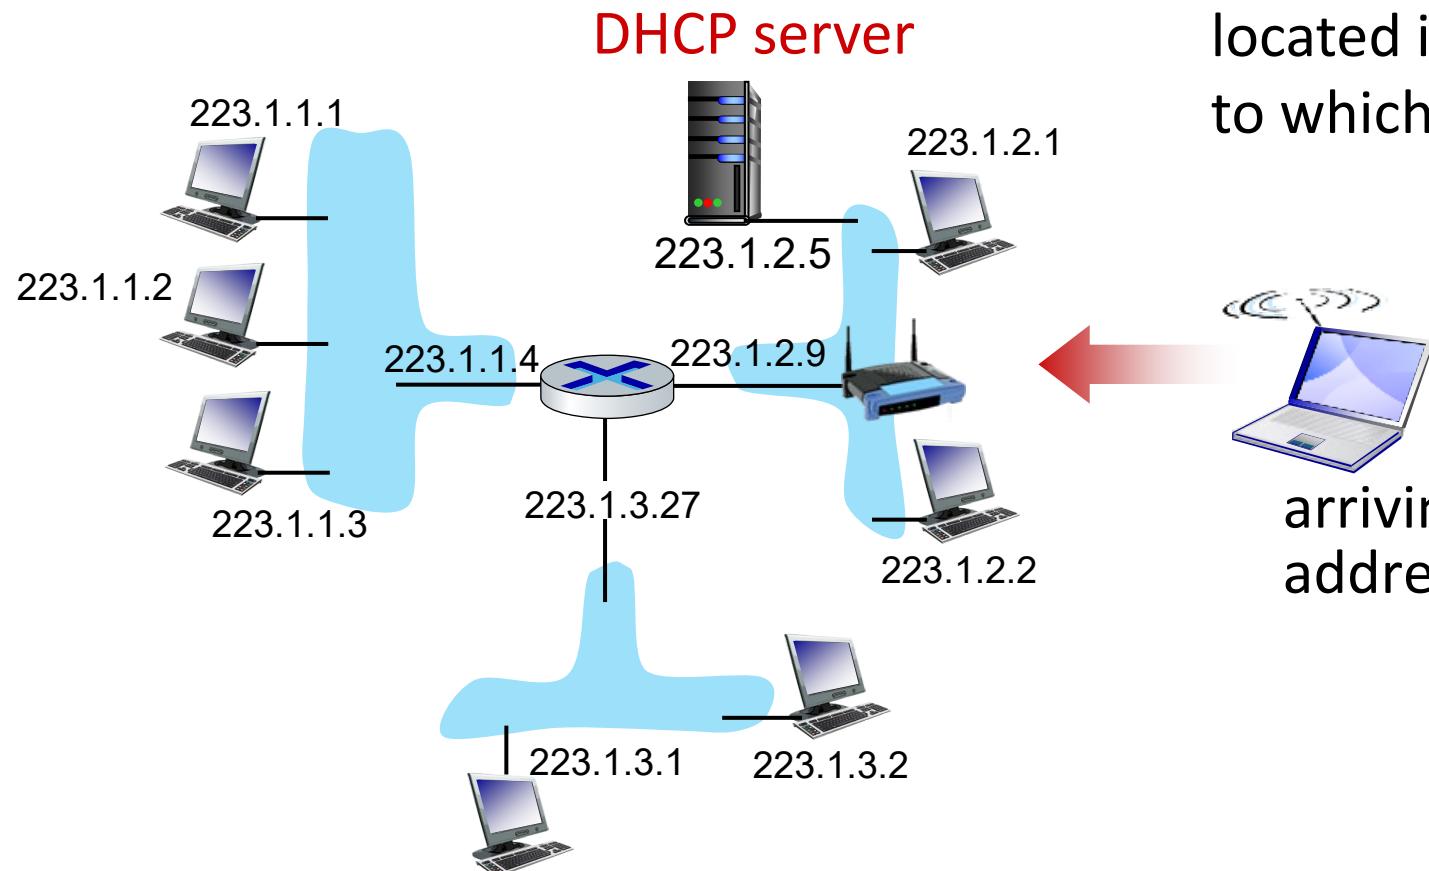

**goal:** host *dynamically* obtains IP address from network server when it “joins” network

- can renew its lease on address in use
- allows reuse of addresses (only hold address while connected/on)
- support for mobile users who join/leave network

## DHCP overview:

- host broadcasts **DHCP discover** msg [optional]
- DHCP server responds with **DHCP offer** msg [optional]
- host requests IP address: **DHCP request** msg
- DHCP server sends address: **DHCP ack** msg

# DHCP client-server scenario

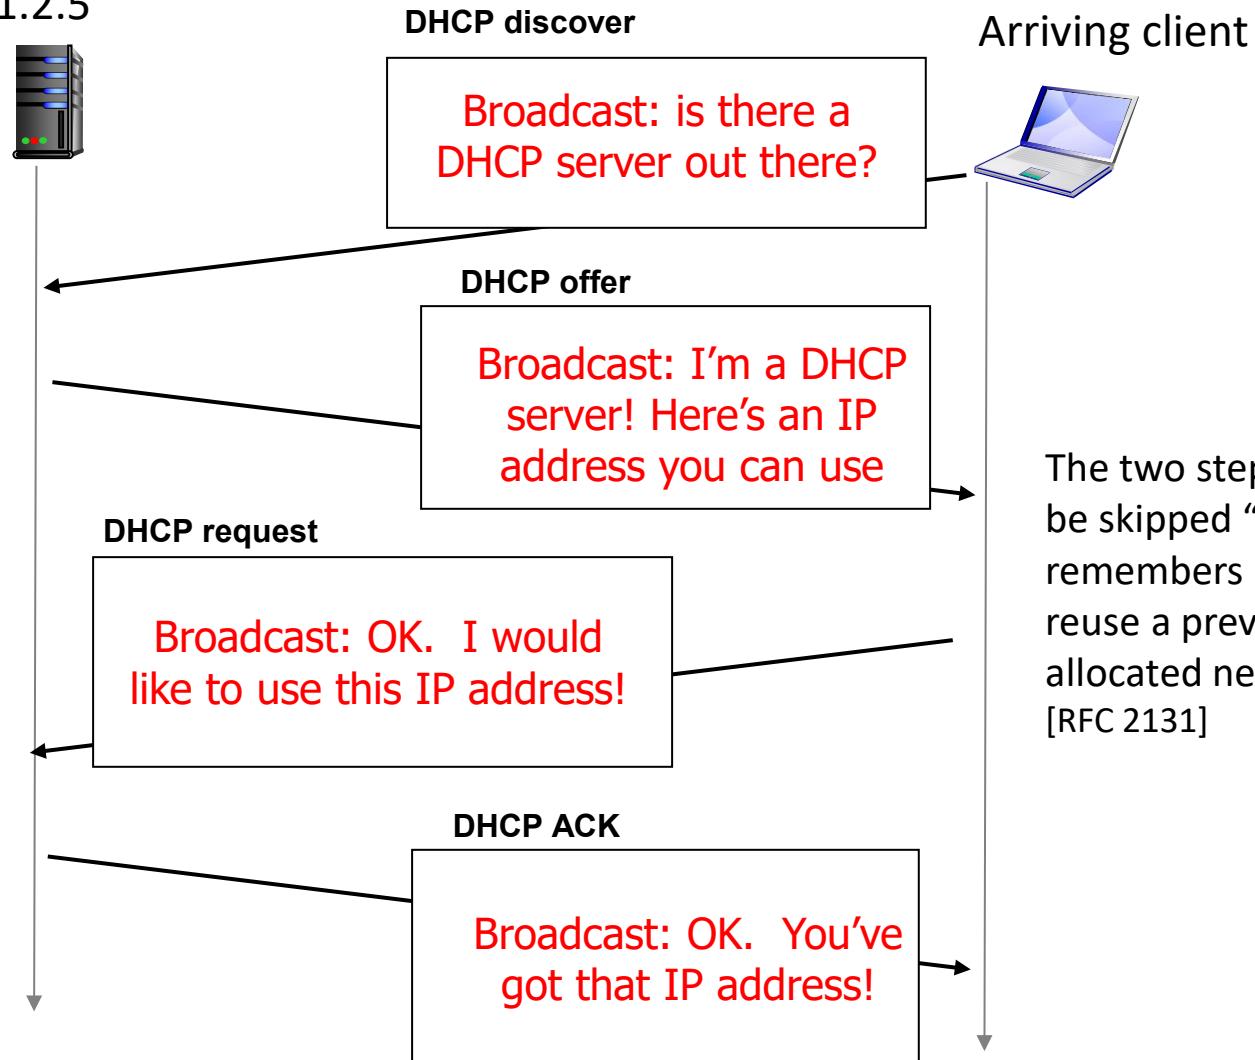

Typically, DHCP server will be co-located in router, serving all subnets to which router is attached

arriving **DHCP client** needs address in this network

# DHCP client-server scenario

DHCP server: 223.1.2.5

# IP addressing: ISP

**Q:** how does an ISP get block of addresses?

**A:** ICANN: Internet Corporation for Assigned Names and Numbers

<http://www.icann.org/>

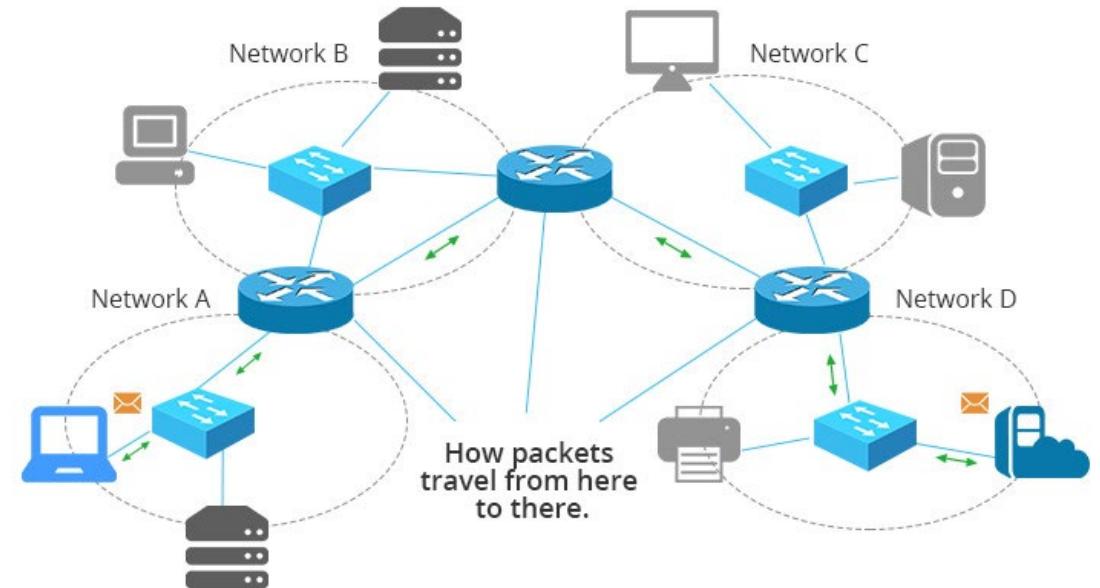

- allocates IP addresses, through 5 regional registries (RRs) (who may then allocate to local registries)
- manages DNS root zone, including delegation of individual TLD (.com, .edu , ...) management

**Q:** are there enough 32-bit IP addresses?

- ICANN allocated last chunk of IPv4 addresses to RRs in 2011
- NAT (next) helps IPv4 address space exhaustion
- IPv6 has 128-bit address space

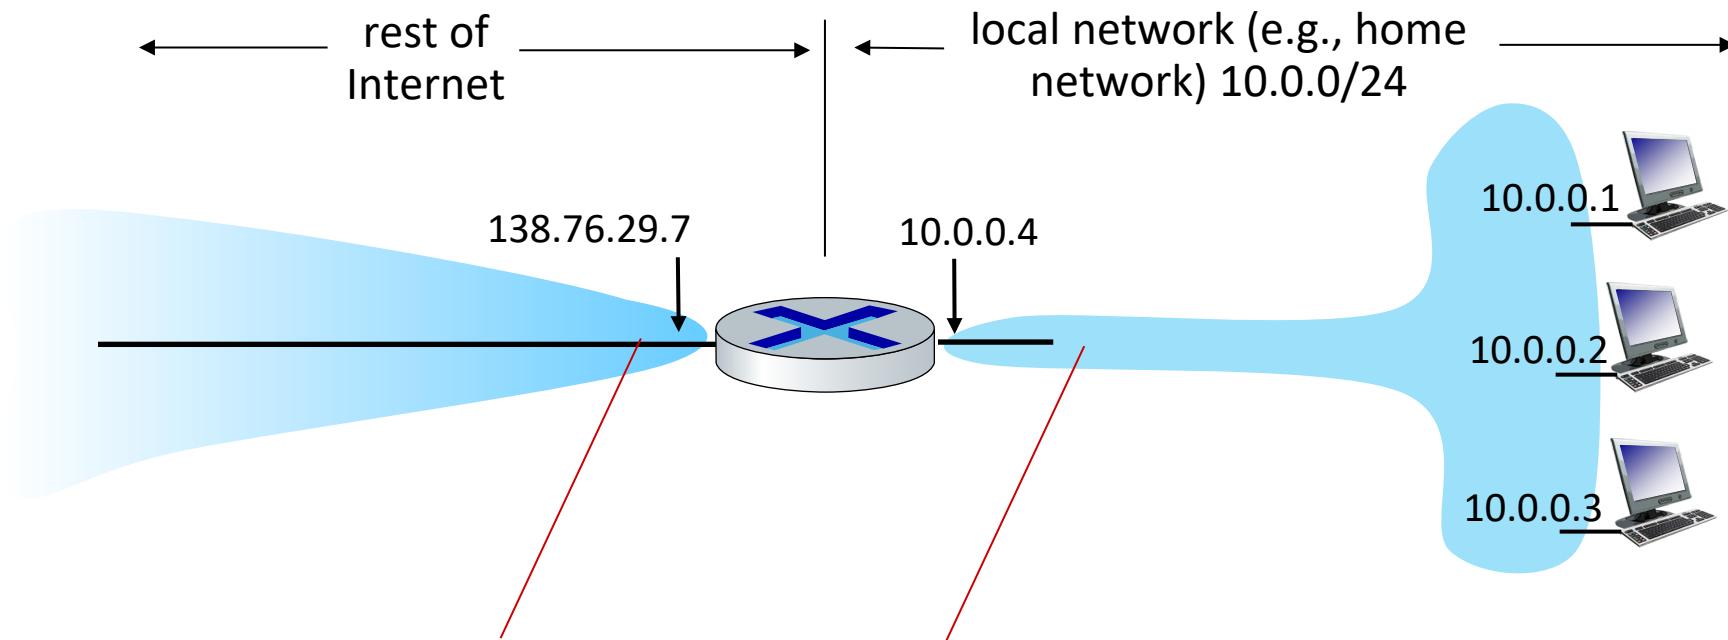

# Network Layer: “data plane” roadmap

- Network layer functions
- Service model
- Networks layer: Internet
- IP Protocol
- IP Addressing
- DHCP
- Network Address Translation (NAT)

# NAT: network address translation

**NAT:** all devices in local network share just **one** IPv4 address as far as outside world is concerned

*all* datagrams *leaving* local network have  
*same* source NAT IP address: 138.76.29.7,  
but *different* source port numbers

datagrams with source or destination in  
this network have 10.0.0/24 address for  
source, destination (as usual)

# NAT: network address translation

- all devices in local network have 32-bit addresses in a “private” IP address space (10/8, 172.16/12, 192.168/16 prefixes) that can only be used in local network
- advantages:
  - just **one** IP address needed from provider ISP for ***all*** devices
  - can change addresses of host in local network without notifying outside world
  - can change ISP without changing addresses of devices in local network
  - security: devices inside local net not directly addressable, visible by outside world

# NAT: network address translation

**2:** NAT router changes datagram source address from 10.0.0.1, 3345 to 138.76.29.7, 5001, updates table
